RPM Best Practices:
Making software distribution easy and predictable
Tom Callaway <tcallawa@redhat.com>
May 10, 2007
About the Presenter

- Leader of Aurora SPARC Linux team (Fedora/SPARC)
- Primary Author of Fedora Packaging Guidelines
- Packager and maintainer for 120+ packages in Fedora Extras
- Chair of Fedora Packaging Committee, member of Fedora Engineering Steering Committee
- Wild and crazy guy
Good Packaging: Important!

- Standardize deployments
  - Know that you installed it
- Simplify environment
  - Know how to find it
- Standards compliance
  - Know what is present
- Sanity retention
  - Know where it is
Packaging in the Red Hat context

- Red Hat uses RPM
- RPM format is Linux Standard (LSB)
- 10+ years of refinements
- Database driven solution
- Dependency tracking
- Built in package verification
- Integrated into RHEL/Fedora
RPM Myths

- Doesn't work well
- Hard to create packages
- Hard to install packages
- Hard to remove packages
- Dependency nightmare
  - (Dependency Hell)
Don't Slay The Dragon

RPM is mostly misunderstood

- Works extremely well
- Package creation is easier than you think
- Easy to install
- Easy to remove
- Good Packages + Good Tools = Profit!
Dependency Resolution: Yum

- RPM Pain Point: Dependency resolution
  - Dependencies make RPM useful, but also complicated.
- RHEL 5 and Fedora use yum to ease the pain
- Metadata is generated from tree of RPM packages
- Yum uses metadata to resolve dependencies
- Only install what you need
- Remove what you don't need anymore
- Red Hat Network uses yum (RHEL 5)
Packaging as a Standard

- Auditing software usage
  - What, when, where?
- Version control
- Kickstart integration
- Minimizes risk
  - Security
  - Rogue applications
Crash Course in RPM Usage

- Binary Package (goldfish-1.0.0-1.i386.rpm)
  - File name is different from package name
- Install package with file name
  - `rpm -ivh goldfish-1.0.0-1.i386.rpm`
    (i for install, v for verbose, h for process hash)
- Query installed package with package name
  - `rpm -ql goldfish`
    (q for query, l for list files)
- Remove package with package name
- `rpm -e goldfish`
  (e for erase)
Source RPM overview

- Source Package (goldfish-1.0.0-1.src.rpm)
  - SRPMs contain sources/components/spec file used to generate binary RPM packages
- Install SRPM package with SRPM file name
  - `rpm -ivh goldfish-1.0.0-1.src.rpm`
    (i for install, v for verbose, h for process hash)
  - Source packages just install source into defined source directory
    - Red Hat default:
      `/usr/src/redhat/SOURCES`
- SRPMs do not go into the RPM database
- Remove installed SRPM with spec file name
  - `rpmbuild --rmsource --rmspec goldfish.spec`
More Source RPM overview

- Making a binary rpm from SRPM:
  - `rpmbuild --rebuild goldfish-1.0.0-1.src.rpm`

- Making a binary rpm from spec file
  - `rpmbuild -ba goldfish.spec`
    (-b for build, -a for all packages, src and bin)

- Making a patched source tree from spec file
  - `rpmbuild -bp goldfish.spec`
    (-b for build, -p for patch only)

- Patched source trees go into the builddir
  - Red Hat default is `/usr/src/redhat/BUILD`

- Building for a different architecture
  - `rpmbuild --target sparc --rebuild goldfish-1.0.0-1.src.rpm`
  - Be careful! Many software programs detect the system type in configure and ignore what rpm told it.
~/.rpmmacros: Use it or else

Do it now. You'll thank me later. So will the kittens.

- Having an ~/.rpmmacros file enables custom macros for your user.
  - Do NOT EVER build RPMS as root. Let me repeat, do NOT EVER build RPMS as root.

- Make a rpmbuild tree in your home directory:
  mkdir -p ~/rpmbuild/{BUILD,RPMS,SOURCES,SPECS,SRPMS}
  mkdir -p ~/rpmbuild/RPMS/{noarch,i386,i686}

- Make an ~/.rpmmacros file:
  %_topdir    %(echo $HOME)/rpmbuild
Other useful ~/rpmmacros additions

- `%_smp_mflags -j3`
  - If your package SPEC has “make %{?_smp_mflags}, then this will tell it to try to build across three CPUs.
  - Why three? Three is a nice odd number that isn't too harsh for uniprocessor systems but enough to expose code that doesn't build well in SMP environments.

- `__arch_install_post /usr/lib/rpm/check-rpaths /usr/lib/rpm/check-buildroot`
  - Fedora has an rpmdevtools package full of, well, rpm development tools.
  - Check-rpaths will make sure that your package doesn't have any hardcoded rpaths (a bad thing)
  - Check-buildroot will make sure none of the packaged files have the buildroot hardcoded (also a bad thing)
Cooking with Spec Files

- Think of a spec file as a recipe
- Lists the contents of the RPMS
- Describes the process to build, install the sources
- Required to make packages
- Very similar to shell script
- Stages:
  - Preamble -> Setup -> Build -> Install -> Clean ->
  - Files -> Changelog
Understanding the Spec File: Preamble

- Initial section
- Defines package characteristics
  - Name/Version/Group/License
  - Release tracks build changes
  - Sources/Patches
  - Requirements
    - Build & Install
  - Summary/Description
  - Custom macro definitions
This program prints hello world on the screen to avoid the “programmers curse”. The Programmers Curse states that unless your first example is “Hello World!”, then you will be cursed, and never able to use that tool.
Understanding the Spec: Setup

- Source tree is generated
- Sources unpacked here
- Patches applied
- Any pre-build actions
- Example of a %setup stage:

  ```
  %prep
  %setup -q
  %patch0 -p1
  ```
Understanding the Spec: Build

- Binary components created
- Use the %configure macro for good defaults
- Build binary bits in sourcedir: rpmbuild -bc helloworld.spec (-b for build, -c for compile and stop)
- Example of a %build section
  
  %build
  %configure
  make
- If your package uses scons, cmake, alter accordingly.
Understanding the Spec: Install

- Creates buildroot
- Lays out filesystem structure
- Puts built files in buildroot
- Cleans up unnecessary installed files
- Example of an %install section

```bash
%install
rm -rf $RPM_BUILD_ROOT
mkdir -p $RPM_BUILD_ROOT%{_bindir}
cp helloworld.sh $RPM_BUILD_ROOT%{_bindir}/helloworld
```

%{_bindir} ?!

- That's just a macro for /usr/bin.
- `rpm --showrc` will show you all the defined macros
- `rpm --eval %{__macroname}` will show you what it means
Understanding the Spec: Clean & Files

- Clean removes the buildroot
- Files: List of package contents
- If its not in %files, its not in the package.
- RPM **WILL** complain about unpackaged files
  - Please, please, please. Don’t ever hack around this and generate files in %post.
- Example of %clean & %files sections

```plaintext
%clean
rm -rf $RPM_BUILD_ROOT

%files
%defattr(-,root,root)
%attr(0755,gold,fish) %{_bindir}/helloworld
```
Understanding the Spec: Changelog

- Used to track package changes
- Not intended to replace source code Changelog
- Provides explanation, audit trail
- Update on EVERY change
- Example of Changelog section:

```
%changelog
* Mon Apr 16 2007 Tom “spot” Callaway <tcallawa@redhat.com> 1.1-2
  - update example package
* Sun May 14 2006 Tom “spot” Callaway <tcallawa@redhat.com> 1.1-1
  - initial package for Red Hat Summit Presentation
```
Best Practices

- K.I.S.S.
- Use patches, not rpm hacks
- Avoid scriptlets, minimize pre/post wherever possible
- Use Changelog
- Look to Fedora package
- Be consistent with macros
Better than Best Practices

- Use rpmlint, fix warnings/errors
- Include configs/scripts as Source files
- Comment!
  - ...but keep it legible
  - Think of the guy who will have to fix your package when you leave.
- Don't ever call rpm from inside a spec file.
  - Remember Ghostbusters? Crossing the streams? Bad.
Good Packages Put You In Control

- Practice makes perfect
- Integration with yum, Red Hat Network Satellite
- Simplify, standardize, save time and sanity
  - Build once, install many.
